

# Oxidation Numbers

$$Fe^{3+} + e^{-} \rightarrow Fe^{2+}$$

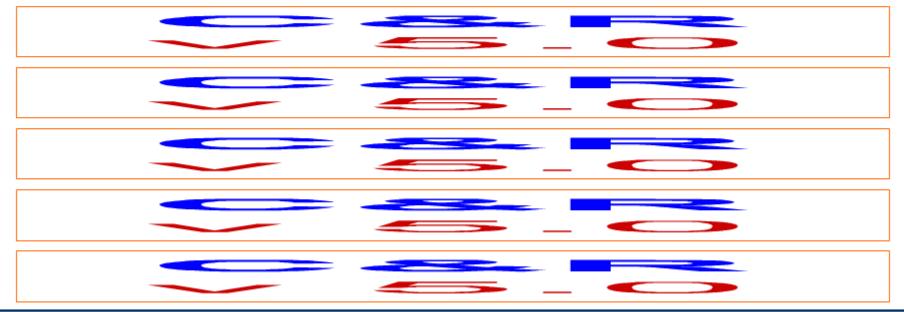

#### **Oxidation numbers**

### Rules for assigning oxidation numbers

The **oxidation number** or **oxidation state** of an atom in a compound is the charge that atom would have if the compound consisted only of separate ions. Click on a rule to see an example.

# Figuring out oxidation numbers

#### Match the atoms to their oxidation states

Fe in Fe<sub>2</sub>O<sub>3</sub>

+3

 $O^{2-}$ 

-2

S in H<sub>2</sub>SO<sub>4</sub>

+6

P in PO<sub>4</sub><sup>3</sup>-

+5

C in CO<sub>2</sub>

+4

## **Changes in oxidation number**

Oxidation numbers can be used to define the processes of oxidation and reduction.

During **oxidation**, the oxidation number **increases**:

$$\begin{array}{c} H_2 \rightarrow 2H^+ + 2e^- \\ \text{oxidation} \\ \text{number} \end{array}$$

During **reduction**, the oxidation number **decreases**:

4 of 6

#### **Oxidation numbers in names**

Oxidation numbers can be used in the names of compounds to indicate which oxidation state a particular element in the compound is in.

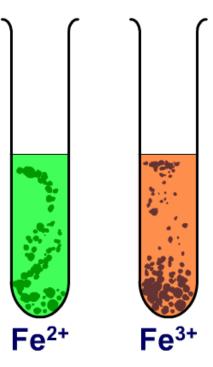

The oxidation state is usually put in parentheses in Roman numerals after the name of the element in question.

For example:

iron(II) hydroxide

Fe(OH)<sub>2</sub>

iron is in oxidation state +2

iron(III) hydroxide

Fe(OH)<sub>3</sub>

iron is in oxidation state +3

#### **Oxidation or reduction?**

## Calculate the oxidation states to answer the questions

Figuring out the change in oxidation state can tell you whether a particular element is oxidized or reduced in a reaction.

Click "start" to see if you can apply this idea.
